*Created by: Eng. Ahmed M. Ayash*

*Modified and Presented By: Eihab S. El-Radie*

## *Lab # 7*

# *Shift, Rotate, Multiplication and Division Instructions*

**Objective:**

- To know more about Assembly language, such Shift, Rotate, Multiplication and Division Instructions.

❖ **Shift and Rotate Instructions**

- Shifting means to move bits right and left inside an operand.
- The following table provides Shift and Rotate Instructions.
- All affecting the Overflow and Carry flags.

SHL	Shift left
SHR	Shift right
SAL	Shift arithmetic left
SAR	Shift arithmetic right
ROL	Rotate left
ROR	Rotate right
RCL	Rotate carry left
RCR	Rotate carry right
SHLD	Double-precision shift left
SHRD	Double-precision shift right

➤ **Logical Shifts and Arithmetic Shifts**

- A logical shift fills the newly created bit position with zero.

- An arithmetic shift fills the newly created bit position with a copy of the number's sign bit.

- Example of Right Logical Shifts and Right Arithmetic Shifts

## SHL Instruction

- The SHL (shift left) instruction performs a logical left shift on the destination operand, filling the lowest bit with 0.

- The first operand in SHL is the destination and the second is the shift count:

*SHL destination, count*

- Operand types for SHL:

- **SHL reg,imm8**
- **SHL mem,imm8**
- **SHL reg,CL**
- **SHL mem,CL**

- Formats shown here also apply to the SHR, SAL, SAR, ROR, ROL, RCR, and RCL instructions.

## Application: Fast Multiplication

- Shifting left 1 bit multiplies a number by 2
- Shifting the integer 5 left by 1 bit yields the product of  $5 * 2^1 = 10$

```
mov dl, 5
shl dl, 1
```

Before: 0 0 0 0 1 0 1 = 5

After: 0 0 0 1 0 1 0 = 10

- Shifting left  $n$  bits multiplies the operand by  $2^n$
- For example,  $5 * 2^2 = 20$

```
mov dl, 5
shl dl, 2 ; DL = 20, CF = 0
```

## SHR Instruction

- The SHR (shift right) instruction performs a logical right shift on the destination operand. The highest bit position is filled with a zero.

## Application: Division

- Shifting right  $n$  bits divides the operand by  $2^n$

```
mov dl, 80 ; DL = 01010000b
shr dl, 1 ; DL = 00101000b = 40, CF = 0
shr dl, 2 ; DL = 00001010b = 10, CF = 0
```

## ✚ SAL and SAR Instructions

- SAL (shift arithmetic left) is identical to SHL.

- SAR (shift arithmetic right) performs a right arithmetic shift on the destination operand.

## ✓ Applications:

### 1. Signed Division

- An arithmetic shift preserves the number's sign.

```

mov dl,-80      ; DL = 10110000b
sar dl,1        ; DL = 11011000b = -40, CF = 0
sar dl,2        ; DL = 11110110b = -10, CF = 0
  
```

### 2. Sign-Extend

- Suppose AX contains a signed integer and you want to extend its sign into EAX. First shift EAX 16 bits to the left, then shift it arithmetically 16 bits to the right:

```

mov ax,-128     ; EAX = ????FF80h
shl eax,16      ; EAX = FF800000h
sar eax,16      ; EAX = FFFFFFFF80h
  
```

## ✚ ROL Instruction

- The ROL (rotate left) instruction shifts each bit to the left. The highest bit is copied into the Carry flag and the lowest bit position.
- No bits are lost.

## ✓ Example:

```

mov al,11110000b
rol al,1        ;AL = 11100001b, CF = 1
  
```

## ✓ Application: Exchanging Groups of Bits

- You can use ROL to exchange the upper (bits 4–7) and lower (bits 0–3) halves of a byte.

```

mov dl,3Fh      ; DL = 00111111b
rol dl,4        ; DL = 11110011b = F3h, CF = 1
  
```

## ✚ ROR Instruction

- The ROR (rotate right) instruction shifts each bit to the right and copies the lowest bit into the Carry flag and the highest bit position.
- No bits are lost.

### ✓ Example:

```
mov al,11110000b
ror al,1          ; AL = 01111000b, CF = 0
```

### ✓ Application: Exchanging Groups of Bits

- You can use ROR to exchange the upper (bits 4–7) and lower (bits 0–3) halves of a byte.

```
mov dl,3Fh       ; DL = 00111111b
ror dl,4         ; DL = 11110011b = F3h, CF = 1
```

## ✚ RCL Instruction

- The RCL (rotate carry left) instruction shifts each bit to the left, copies the Carry flag to the LSB, and copies the MSB into the Carry flag.

### ✓ Example:

```
clc             ; clear carry, CF = 0
mov bl,88h     ; CF = 0 ,BL = 10001000b
rcl bl,1       ; CF = 1 ,BL = 00010000b
rcl bl,1       ; CF = 0 ,BL = 00100001b
```

## ✚ RCR Instruction

- The RCR (rotate carry right) instruction shifts each bit to the right, copies the Carry flag into the MSB, and copies the LSB into the Carry flag.

### ✓ Example:

```
stc           ; set carry, CF = 1
mov ah,10h    ; CF = 1, AH = 00010000b
rcr ah,1      ; CF = 0, AH = 10001000b
```

## SHLD Instruction

- The SHLD (shift left double) instruction shifts a destination operand a given number of bits to the left.
- The bit positions opened up by the shift are filled by the most significant bits of the source operand.
- Only the destination is modified, not the source.

- Syntax:

`SHLD dest, source, count`

- Operand types:

- `SHLD reg16, reg16, CL/imm8`
- `SHLD mem16, reg16, CL/imm8`
- `SHLD reg32, reg32, CL/imm8`
- `SHLD mem32, reg32, CL/imm8`

### Example:

```
.data
wval WORD 9BA6h
.code
mov ax, 0AC36h
shld wval, ax, 4
```

## SHRD Instruction

- The SHRD (shift right double) instruction shifts a destination operand a given number of bits to the right.
- The bit positions opened up by the shift are filled by the least significant bits of the source operand.

✓ **Example:**

```

mov ax, 234Bh
mov dx, 7654h
shrd ax, dx, 4

```

❖ **Multiplication and Division Instructions**

✚ **MUL Instruction**

- The MUL (unsigned multiply) instruction comes in three versions:
  - The first version multiplies an 8-bit operand by the AL register.
  - The second version multiplies a 16-bit operand by the AX register.
  - The third version multiplies a 32-bit operand by the EAX register.
- The multiplier and multiplicand must always be the same size, and the product is twice their size.
- The three formats accept register and memory operands, but not immediate operands:
  - MUL *reg/mem8*
  - MUL *reg/mem16*
  - MUL *reg/mem32*

Multiplicand	Multiplier	Product
AL	reg/mem8	AX
AX	reg/mem16	DX:AX
EAX	reg/mem32	EDX:EAX

- MUL sets the Carry and Overflow flags if the upper half of the product is not equal to zero.

✓ **Example1: Multiply 16-bit var1 (2000h) \* var2 (100h)**

```

.data
var1 WORD 2000h
var2 WORD 100h
.code
mov ax, var1
mul var2 ; DX:AX = 00200000h, CF = OF = 1

```

✓ **Example2: Multiply EAX (12345h) \* EBX (1000h)**

```

mov eax, 12345h
mov ebx, 1000h
mul ebx ; EDX:EAX = 0000000012345000h, CF=OF=0

```

## ✚ DIV Instruction

- The DIV (unsigned divide) instruction performs 8-bit, 16-bit, and 32-bit unsigned integer division.
- The single register or memory operand is the divisor.
- The formats are
  - DIV *reg/mem8*
  - DIV *reg/mem16*
  - DIV *reg/mem32*

Dividend	Divisor	Quotient	Remainder
AX	<i>reg/mem8</i>	AL	AH
DX:AX	<i>reg/mem16</i>	AX	DX
EDX:EAX	<i>reg/mem32</i>	EAX	EDX

### ✓ Example1: Divide AX = 8003h by CX = 100h, using 16-bit operands

```
mov dx,0           :clear dividend, high
mov ax,8003h       :dividend, low
mov cx,100h        :divisor
div cx             ; AX = 0080h, DX = 0003h (Remainder)
```

### ✓ Example2: Same division, using 32-bit operands

```
mov edx,0          :clear dividend, high
mov eax,8003h      :dividend, low
mov ecx,100h       :divisor
div ecx           ; EAX = 00000080h, EDX = 00000003h
```

## Lab work:

### Excercise1:

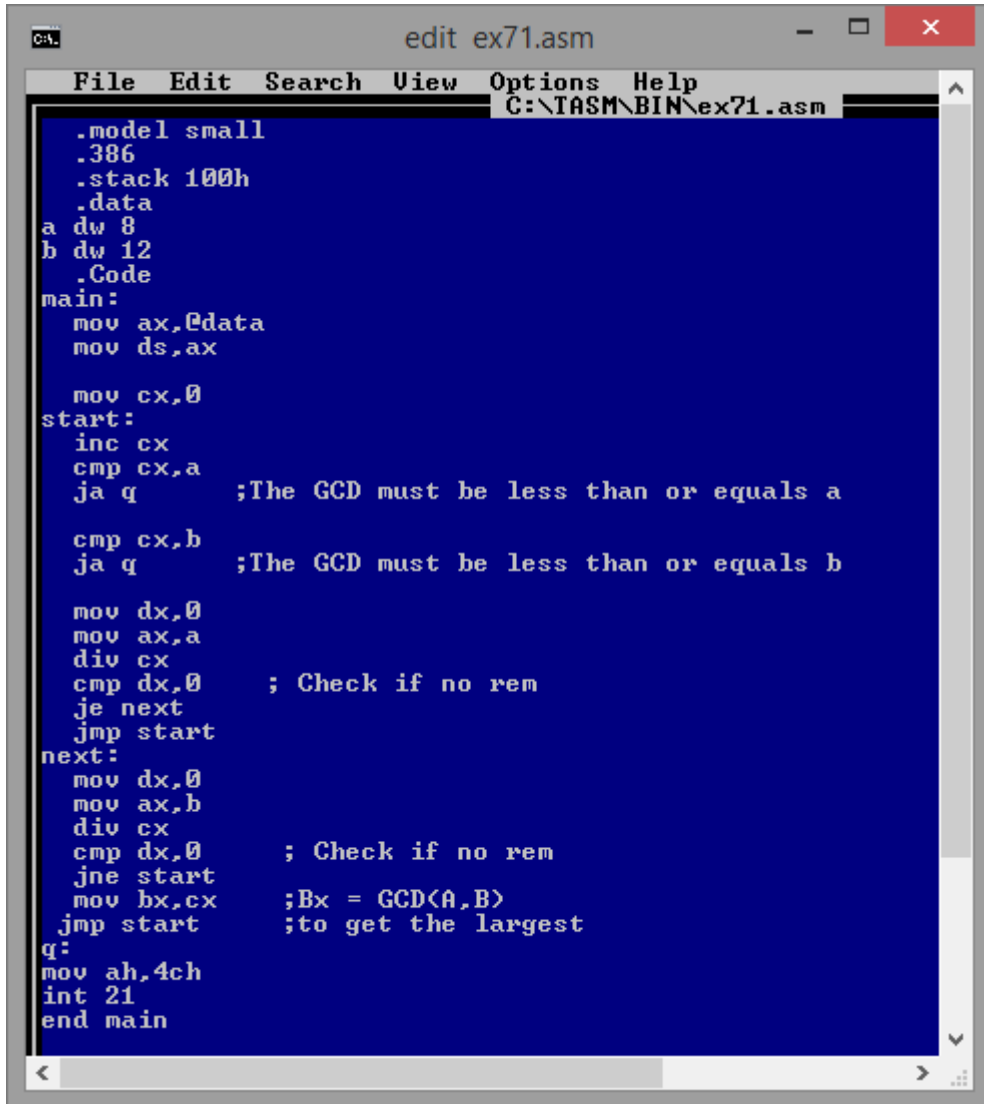

The greatest common divisor of two integers is the largest integer that will evenly divide (without a remainder) both integers. The GCD algorithm involves integer division in a loop, described by the following c++ code:

```
int GCD(int x , int y)
{
  x = abs (x);
  y = abs (y);
  do {
    int n = x % y;
    x = y;
    y = n;
  } while (y > 0) ;
  return x ;
}
```

Write an assembly program that determines the gcd (greatest common divisor) of two positive integer numbers

This solution is just for positive integers and don't follow the previous algorithm. **In your homework** you should implement the algorithm exactly.

```
.model small
.386
.stack 100h
.data
a dw 8
b dw 12
.Code
main:
mov ax,@data
mov ds,ax

mov cx,0
start:
inc cx
cmp cx,a
ja q ;The GCD must be less than or equals a

cmp cx,b
ja q ;The GCD must be less than or equals b

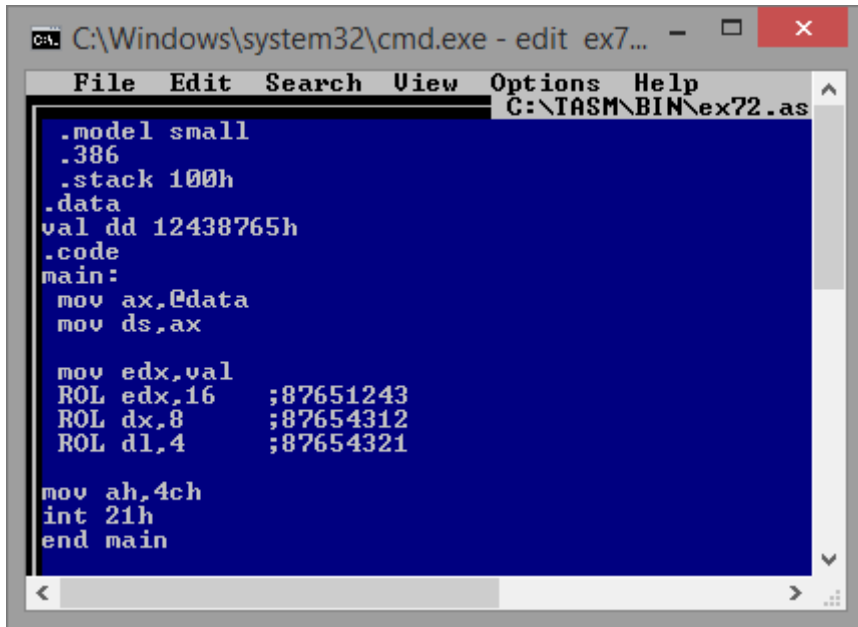

mov dx,0
mov ax,a
div cx
cmp dx,0 ; Check if no rem
je next
jmp start
next:
mov dx,0
mov ax,b
div cx
cmp dx,0 ; Check if no rem
jne start
mov bx,cx ;Bx = GCD(A,B)
jmp start ;to get the largest
q:
mov ah,4ch
int 21
end main
```

**For HW:**

1. Modify the code so you can find GCD of signed integers.
2. Write some instructions to get the absolute of two integers.
3. Using your program, find: GCD (12,8) , GCD(24,72), GCD(-24,72)

## Excercise2:

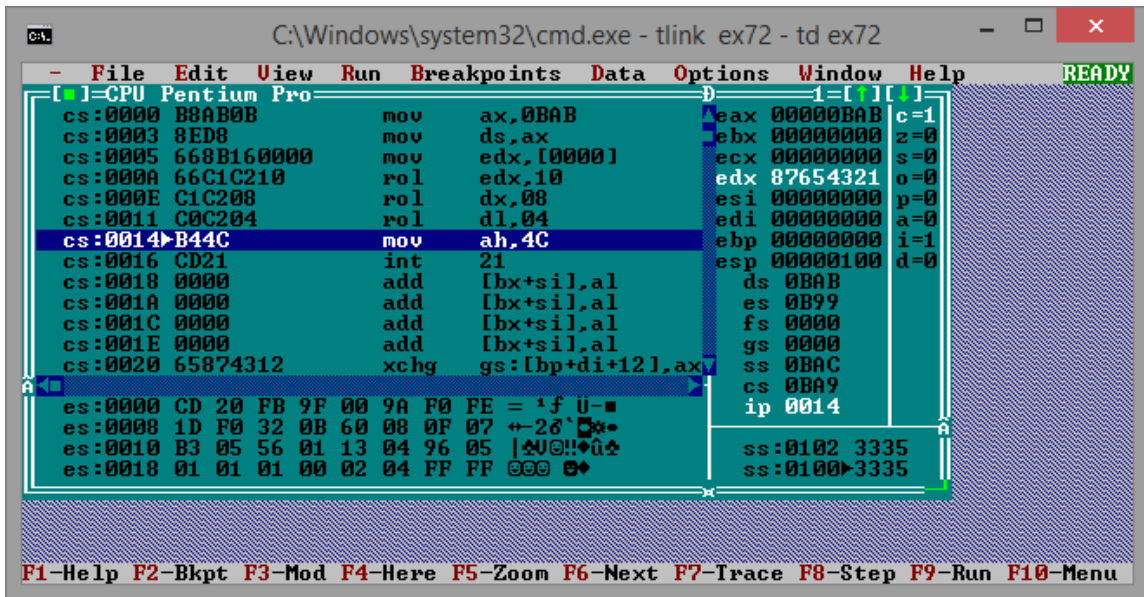

Write an assembly code to convert the number 12438765h to 87654321h.

```

HW: What is the result if we use ROR instead of ROL?

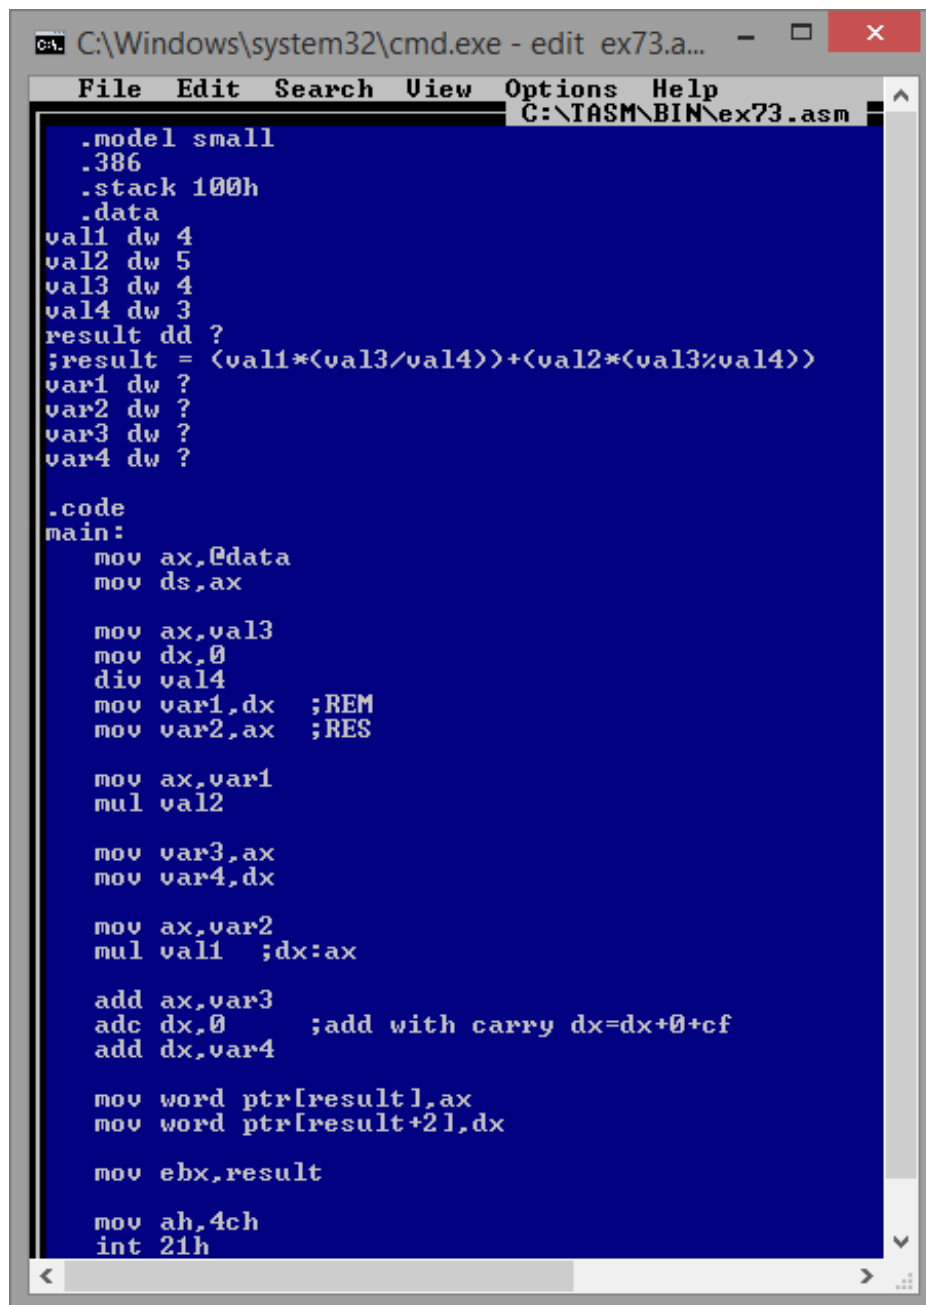

### Excercise3:

Write an assembly code to evaluate the following expression:

$$(val1*(val3/val4)) + (val2*(val3\%val4))$$

Use these values:

```
val1 dw 4
val2 dw 5
val3 dw 4
val4 dw 3
result dd ?
```

```
C:\Windows\system32\cmd.exe - edit ex73.a...
File Edit Search View Options Help

.model small
.386
.stack 100h
.data
val1 dw 4
val2 dw 5
val3 dw 4
val4 dw 3
result dd ?
;result = (val1*(val3/val4))+(val2*(val3%val4))
var1 dw ?
var2 dw ?
var3 dw ?
var4 dw ?

.code
main:
    mov ax,@data
    mov ds,ax

    mov ax,val3
    mov dx,0
    div val4
    mov var1,dx ;REM
    mov var2,ax ;RES

    mov ax,var1
    mul val2

    mov var3,ax
    mov var4,dx

    mov ax,var2
    mul val1 ;dx:ax

    add ax,var3
    adc dx,0 ;add with carry dx=dx+0+cf
    add dx,var4

    mov word ptr[result],ax
    mov word ptr[result+2],dx

    mov ebx,result

    mov ah,4ch
    int 21h
```

## Homework:

1. Write an assembly code to convert a binary string into hexadecimal value. If the binary String is greater than 32 digits length a value zero must be returned. Use this value declaration:

```
B_Val db '10001111', '$'
```

2. Write an assembly code to find the power of any integer to any integer using **mul** instruction. Use these values for testing:

```
base db 3h
power db 5h
result dd ? ;3^5 =243 = F3H
```
